

Answers to Problem 27, Chemistry 301X - 2006

Step 1:

break π and $\text{H}-\text{Cl}$ = $66 + 103 = 169$ kcal/mol

make $\text{C}-\text{H}$ = ~ 96

So, this reaction is endothermic by at least $169 - 96 = 73$ kcal/mol (and then there are those charges.....)

Step 2:

make $\text{C}-\text{Cl}$ only, so this reaction is exothermic by about 85 kcal/mol (and those charges go away).

What is the thermochemistry of the overall process?
