Homometric Sets
myoung@smith.edu

Two sets of points, A and B are said to be *homometric* if the list of distances between pairs of points in A is the same as the list of distances between pairs of points in B . The size and number of homometric sets of points on a cycle are well studied by crystallographers and music theorists. This talk will ask and discuss some questions about the size of homometric sets on other types of graphs.
